

Scheme is a Dialect of Lisp

What are people saying about Lisp?

- •"If you don't know Lisp, you don't know what it means for a programming language to be powerful and elegant."
 - Richard Stallman, created Emacs & the first free variant of UNIX
- "The only computer language that is beautiful."
 - -Neal Stephenson, DeNero's favorite sci-fi author
- •"The greatest single programming language ever designed."
 - -Alan Kay, co-inventor of Smalltalk and OOP (from the user interface video)

Scheme Expressions

Scheme programs consist of expressions, which can be:

- Primitive expressions: 2 3.3 true + quotient
- Combinations: (quotient 10 2) (not true)

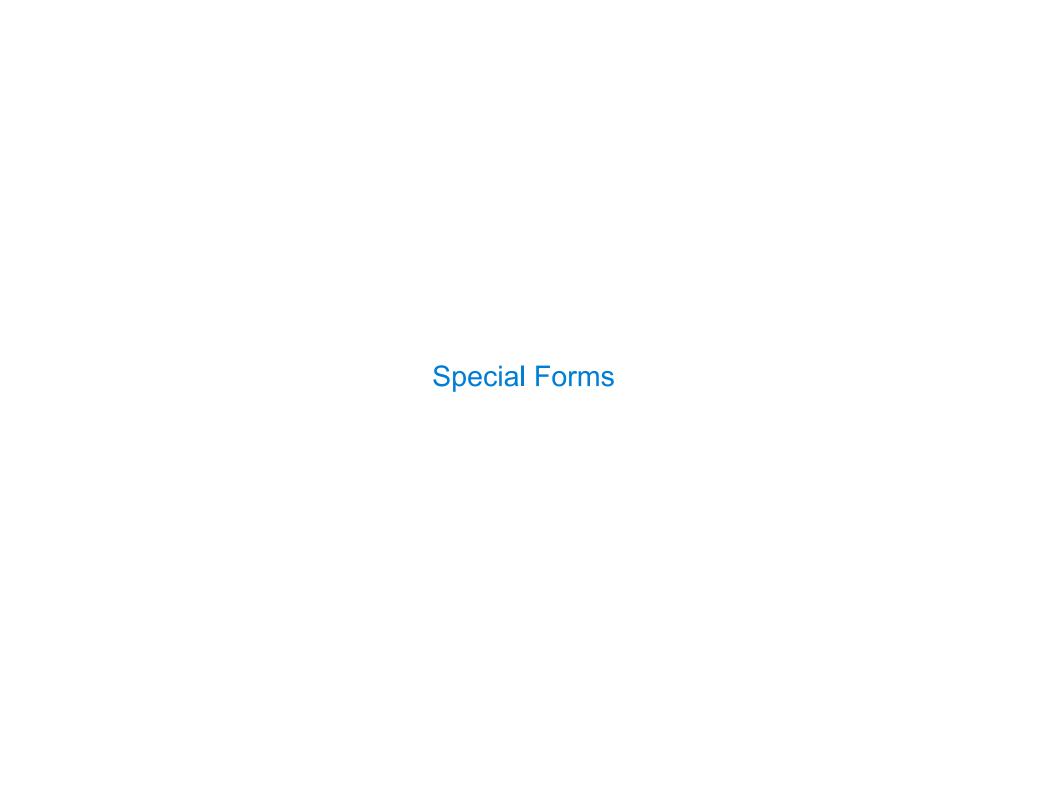

Numbers are self-evaluating; symbols are bound to values

Call expressions include an operator and 0 or more operands in parentheses

```
> (quotient 10 2)
5
> (quotient (+ 8 7) 5)
3
> (quotient (+ 8 7) 5)
Graph (i.e., function)

Combinations can span multiple lines
(spacing doesn't matter)

(Demo)
```

Special Forms

```
A combination that is not a call expression is a special form:
                                                                        Evaluation:
• if expression:
                  (if consequent> <alternative>)
                                                                      (1) Evaluate the
                                                                    predicate expression
• and and or:
                  (and <e1> ... <en>), (or <e1> ... <en>)
                                                                     (2) Evaluate either
Binding symbols: (define <symbol> <expression>)
                                                                     the consequent or
                                                                        alternative
• New procedures: (define (<symbol> <formal parameters>) <body>)
                     > (define pi 3.14)
                                          The symbol "pi" is bound to 3.14 in the
                     > (* pi 2)
                                                        global frame
                     6.28
                     > (define (abs x)
                                          A procedure is created and bound to the
                         (if (< x 0))
```

(- x) x))

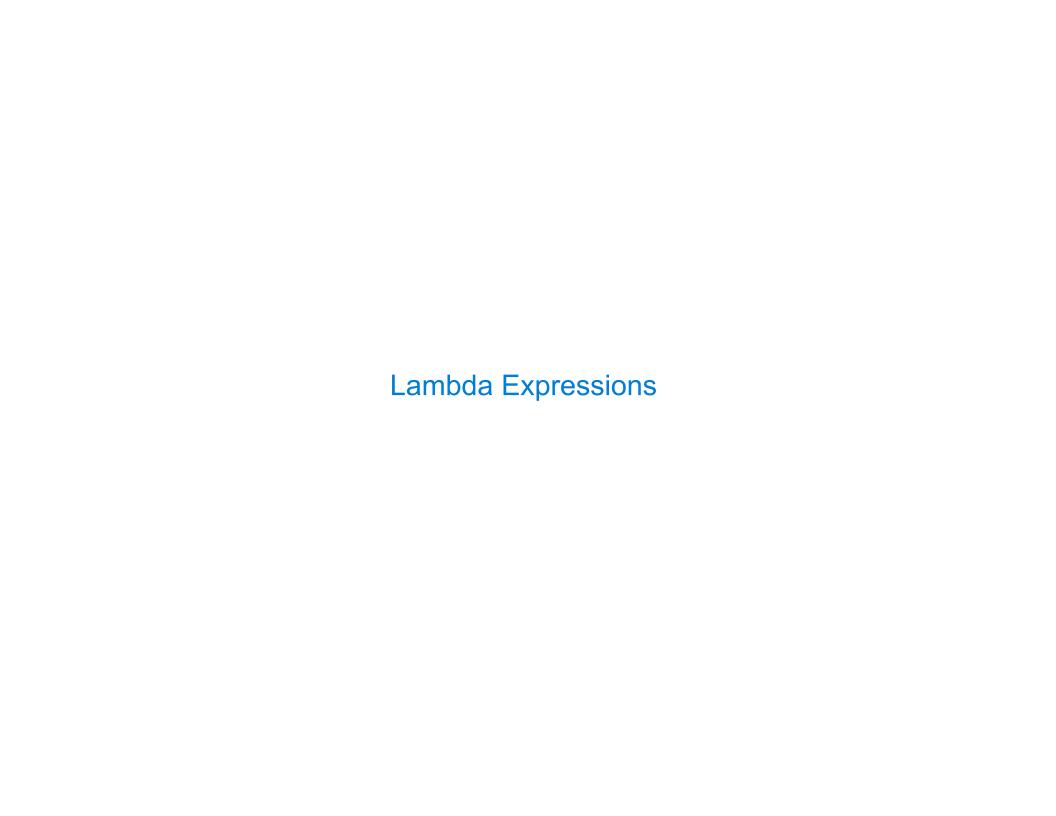

(abs -3)

(Demo)

symbol "abs"

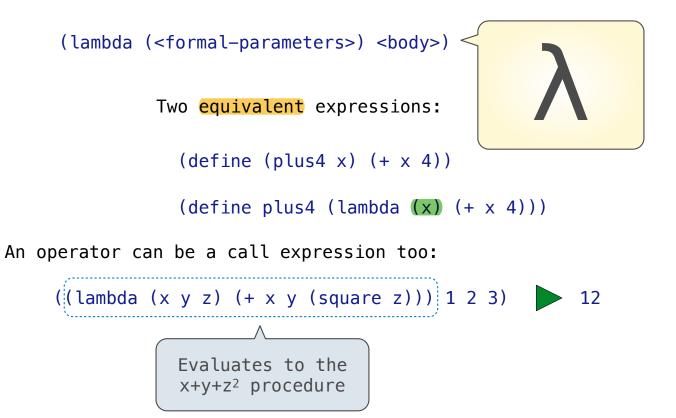

Scheme Interpreters

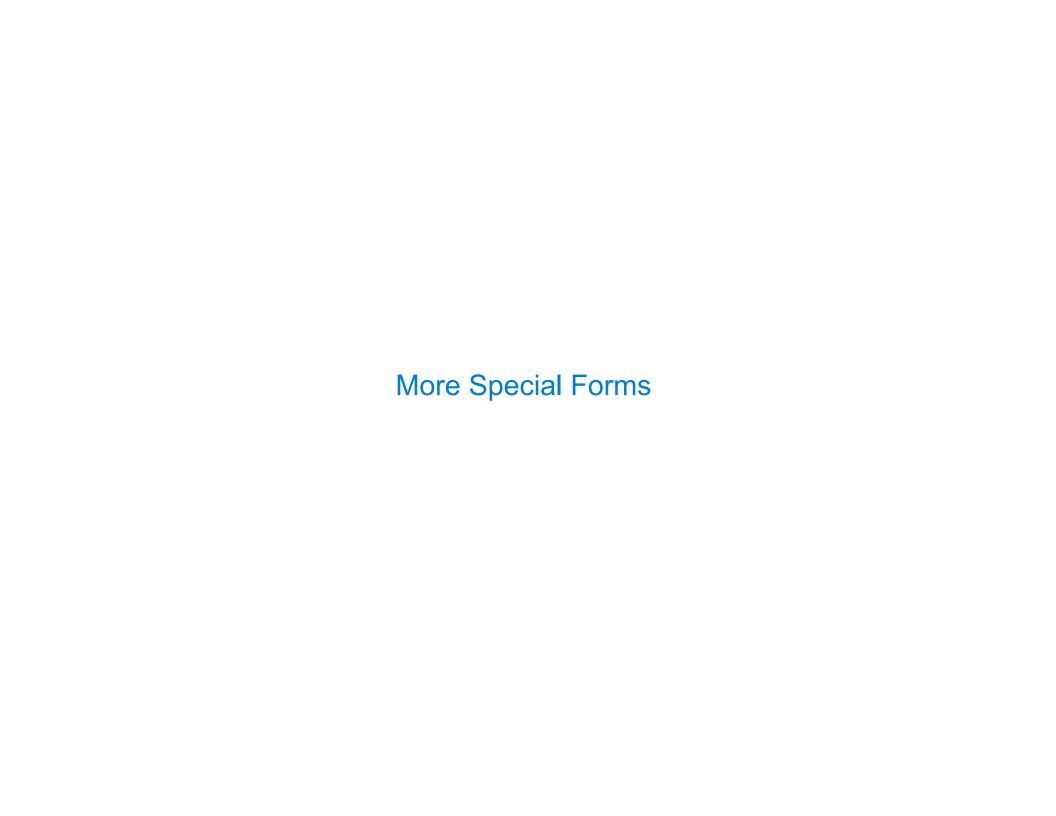

(Demo)

Lambda Expressions

Lambda expressions evaluate to anonymous procedures

Cond & Begin

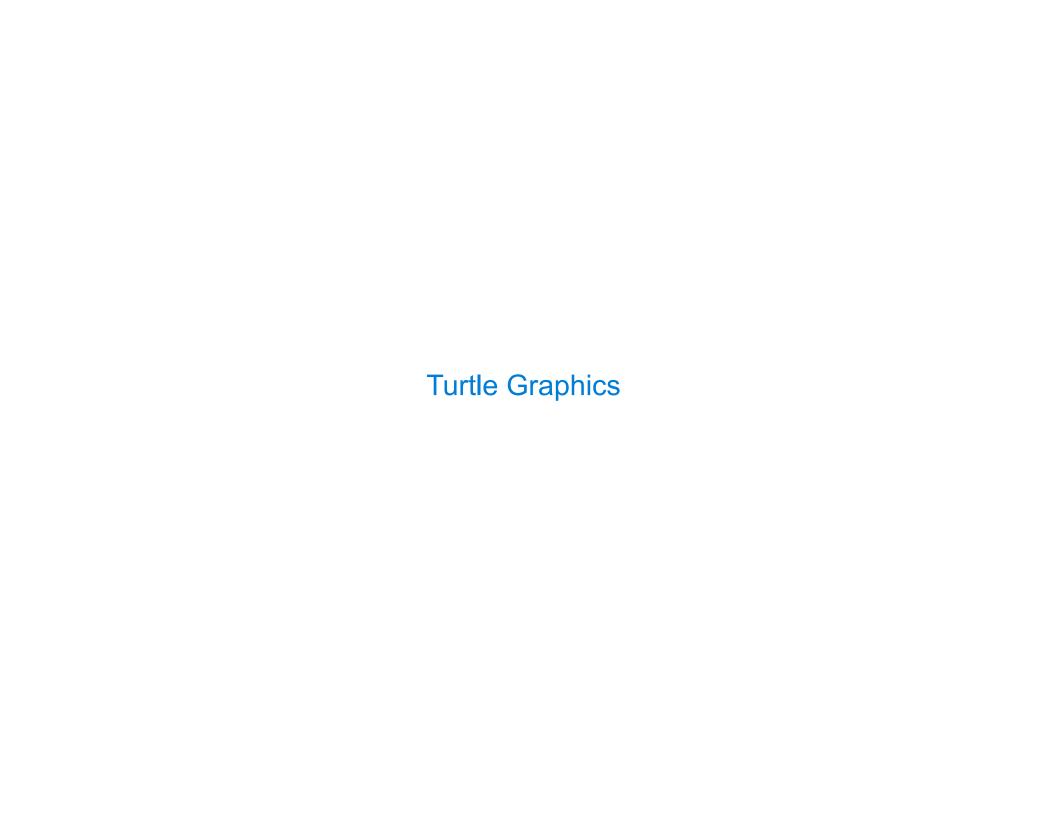

The cond special form that behaves like if-elif-else statements in Python

The begin special form combines multiple expressions into one expression

Let Expressions

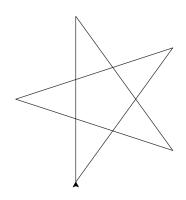

The let special form binds symbols to values temporarily; just for one expression

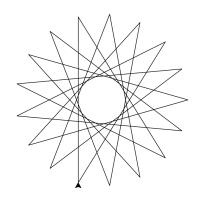

13

Drawing Stars

(forward 100) or (fd 100) draws a line (right 90) or (rt 90) turns 90 degrees

(Demo)

Sierpinski's Triangle
